Allison Valdez
Flowchart Lab

This Flow Chart illustrates how a Junior Developer might plan a new implementation of a feature for a mobile banking app. The goal of the app is to help users set and track their saving goals within the app, without the use of external applications or aids. This is to provide all features central within the app to increase user engagement and reduce the likelihood of them leaving without completing goals. Once logged in, the mobile app should allow a user to: create a sole savings goal, track the saving's progress, and display notifications as the goal's deadline approaches. As standard with every banking app, on each user entry proper error handling should occur to prevent cybersecurity threats.

The chart begins with either the user selecting to create a new savings goal or choosing to provide an update to a previous entry. Through proper error handing, the user should only be able to enter only numeric monetary values and dates for the input, such as the desired savings amount and ending date. Again, this is to prevent errors triggering the app to crash or hacking attempts in the backend. Upon entry, the app should save the user's input in the background database. The application should display notifications and reminders as the goal's target date approaches periodically to keep the user informed and foster engagement.

After an initial entry, saving progress is updated by either manual user entry, or automatic transfers by the system to fund the account. This feature will allow user autonomy to choose how they record their progress and provide updates to the database. The system should be able to perform automatic bank transfers to the saving account after initial set up. Again, this should be performed with proper error handling. Each update should trigger a recalculation of both the user's progress and deadline to check verify if the goal was met or not.

Once the goal is met, a notification should be provided to the user congratulating them of goal completion. It should prompt the user to either end the application or enter a new goal. If the goal was not met, the system should prompt for a new target date or modify the savings goal amount. Note, before this point, the system should have already sent prior notifications to the user to prevent nongoal completion. It should have given date reminders and savings amount prompts to provide entries. With proper error handling, the backend should update the goal amount, relevant deadlines for continual tracking.
